Python Programming Fundamentals Cheat Sheet

| Package/Method | Description | Syntax and Code Example |
|------------------|---|---|
| AND | Returns 'True' if both statement1 and statement2 are 'True'. Otherwise, returns 'False'. | <pre>Example: marks = 90 attendance_percentage = 87 if marks >= 80 and attendance_percentage >= 85: print("qualify for honors") else: print("Not qualified for honors") # Output = qualify for honors</pre> |
| Class Definition | Defines a blueprint for creating objects and defining their attributes and behaviors. | <pre>Syntax: class ClassName: # Class attributes and methods Example: class Person: definit(self, name, age): self.name = name self.age = age</pre> |
| Define Function | A 'function' is a reusable block of code that performs a specific task or set of tasks when called. | Syntax: def function_name(parameters): # Function body Example: def greet(name): print("Hello,", name) |

|------------------|--|---|
| | | |
| | | |
| | | |
| | | |
| | | |
| | | Syntax: |
| | | variable1 == variable2 |
| | | valiable1 valiable2 |
| | | |
| | | |
| | | |
| | | |
| | | |
| | | |
| | | Example 1: |
| | | |
| | | 5 == 5 |
| | | |
| | | |
| | | |
| Equal(==) | Checks if two values are equal. | |
| | | |
| | | |
| | | |
| | | returns True |
| | | Example 2: |
| | | |
| | | age = 25 age == 30 |
| | | |
| | | |
| | | |
| | | |
| | | |
| | | |
| | | |
| | | returns False |
| For Loop | A 'for' loop repeatedly executes a block of code for a specified | Syntax: |
| 1 of Loop | A 'for' loop repeatedly executes a block of code for a specified number of iterations or over a sequence of elements (list, range, | |
| | string, etc.). | for variable in sequence: # Code to repeat |
| | | |
| | | |
| | | |
| | | |
| | | |
| | | |
| | | Formula 1. |
| | | Example 1: |
| | | for num in range(1, 10): print(num) |
| | | print(num) |
| | | |
| | | |
| | | |
| | | |
| | | |
| | | |
| | | F 12 |
| | | Example 2: |
| | | fruits = ["apple", "banana", "orange", "grape", "kiwi"] for fruit in fruits: |
| | | for fruit in fruits: print(fruit) |
| | | |

| Function Call A function call is the act of assessing the code within the function using the previded arguments. Syntax Variable: greet ("Alice") Syntax Variable: 5 >= 5 and 0 >= 5 Greater Than or Equal Checks if the value of variable lis greater than or equal to variable: greet ("Alice") Fourtier True Example: greater Than or Equal Checks if the value of variable lis greater than or equal to returns True Example 2: quartity = 308 quartity >= 7188 quartity | /10/25, /:15 AW | aı | DOULDIANK |
|---|------------------------------|--|--|
| Function Call A function call is the act of executing the code within the function using the provided arguments. Example: greet('Alice') Syntax: vertable1 >= variable2 Example 1: 5 >= 5 and 9 >= 5 Checks if the value of variable1 is greater than or equal to variable2. Checks if the value of variable1 is greater than variable2. Syntax: vertable2 = variable2. Checks if the value of variable1 is greater than or equal to returns True Example 2: quantity = 386 quantity >= 864.timen Checks if the value of variable1 is greater than variable2. Syntax: | | | |
| Greater Than or Equal To(>=) Checks if the value of variable1 is greater than or equal to variable2. Example 1: 5 >= 5 and 9 >= 5 returns True Example 2: quantity = 105 minimum = 109 quantity >= minimum returns True Greater Than(>) Checks if the value of variable1 is greater than variable2. Syntax: | Function Call | A function call is the act of executing the code within the function using the provided arguments. | function_name(arguments) Example: |
| | Greater Than or Equal To(>=) | Checks if the value of variable 1 is greater than or equal to variable 2. | <pre>returns True Example 2: quantity = 105 minimum = 100 quantity >= minimum</pre> |
| | Greater Than(>) | Checks if the value of variable1 is greater than variable2. | |

| | | Example 1: 9 > 6 returns True Example 2: age = 20 max_age = 25 age > max_age |
|--------------|---|--|
| | | returns False |
| | | Syntax: if condition: #code block for if statement |
| If Statement | Executes code block `if` the condition is `True`. | Example: if temperature > 30: print("It's a hot day!") |
| If-Elif-Else | Executes the first code block if condition1 is `True`, otherwise checks condition2, and so on. If no condition is `True`, the else block is executed. | Syntax: if condition1: # Code if condition1 is True elif condition2: # Code if condition2 is True else: # Code if no condition is True |
| | | Example: score = 85 # Example score if score >= 90: print("You got an A!") elif score >= 80: print("You got a B.") else: print("You need to work harder.") # Output = You got a B. |

                                                                                                            returns True
Loop Controls
                              'break' exits the loop prematurely. 'continue' skips the rest of the
                                                                                                            Syntax:
                             current iteration and moves to the next iteration.
                                                                                                                   for: # Code to repeat
if # boolean statement
break
                                                                                                                   for: # Code to repeat
if # boolean statement
                                                                                                                             continue
                                                                                                            Example 1:
                                                                                                                    for num in range(1, 6):
                                                                                                                        if num == 3:
                                                                                                                        break
print(num)
                                                                                                            Example 2:
                                                                                                                   for num in range(1, 6):
    if num == 3:
        continue
                                                                                                                         print(num)
```

about:blank 6/10

| 1 | I | |
|---------------|--|---|
| | | |
| | | |
| | | |
| | | Syntax: |
| | | not variable |
| | | |
| | | |
| | | |
| NOT | Returns `True` if variable is `False`, and vice versa. | Example: isLocked = False |
| | | print(not isLocked) |
| | | |
| | | |
| | | metrome Toyo if the venichle is Folco (i.e. vollected) |
| | | returns True if the variable is False (i.e., unlocked). |
| | | Syntax: variable1 != variable2 |
| | | Validate1 :- Validate2 |
| | | |
| | | |
| | | |
| | | Example: |
| | | a = 10 b = 20 |
| | | a != b |
| | | |
| Not Equal(!=) | Checks if two values are not equal. | |
| | | |
| | | returns True |
| | | Example 2: |
| | | count=0 count != 0 |
| | | |
| | | |
| | | |
| | | returns False |

9/10/25, 7:15 AM about:blank

```
Syntax:
                                                                                                                             object_name = ClassName(arguments)
Object Creation
                               Creates an instance of a class (object) using the class constructor.
                                                                                                                     Example:
                                                                                                                             person1 = Person("Alice", 25)
                                                                                                                     Syntax:
                                                                                                                             statement1 or statement2
                                                                                                                     Example:
                               Returns 'True' if either statement1 or statement2 (or both) are
                                                                                                                             "Farewell Party Invitation"
OR
                                                                                                                             grade = 12
if grade == 11 or grade == 12:
    print("Farewell Party Invitation")
                               'True'. Otherwise, returns 'False'.
                                                                                                                             else:
                                                                                                                                  print("Not eligible")
                                                                                                                     returns True
range()
                               Generates a sequence of numbers within a specified range.
                                                                                                                     Syntax:
                                                                                                                             range(stop)
range(start, stop)
range(start, stop, step)
                                                                                                                     Example:
                                                                                                                             range(5) #generates a sequence of integers from 0 to 4.
range(2, 10) #generates a sequence of integers from 2 to 9.
range(1, 11, 2) #generates odd integers from 1 to 9.
```

about:blank 8/10

| Return Statement | `Return` is a keyword used to send a value back from a function to its caller. | <pre>Syntax: return value Example: def add(a, b): return a + b result = add(3, 5)</pre> |
|-------------------------------|---|--|
| Try-Except Block | Tries to execute the code in the try block. If an exception of the specified type occurs, the code in the except block is executed. | <pre>Syntax: try: # Code that might raise an exception except ExceptionType: # Code to handle the exception Example: try: num = int(input("Enter a number: ")) except ValueError: print("Invalid input. Please enter a valid number.")</pre> |
| Try-Except with Else Block | Code in the 'else' block is executed if no exception occurs in the try block. | <pre>Syntax: try: # Code that might raise an exception except ExceptionType: # Code to handle the exception else: # Code to execute if no exception occurs Example: try: num = int(input("Enter a number: ")) except ValueError: print("Invalid input. Please enter a valid number") else: print("You entered:", num)</pre> |

| 9/10/25, 7:15 AM | | al | bout:blank | |
|------------------|-------------------------------|---|---|--|
| | | | | |
| | Try-Except with Finally Block | Code in the `finally` block always executes, regardless of whether an exception occurred. | <pre>Example: try: # Code that might raise an exception except ExceptionType: # Code to handle the exception finally: # Code that always executes Example: try: file = open("data.txt", "r") data = file.read() except FileNotFoundError: print("File not found.") finally: file.close()</pre> | |
| | While Loop | A `while` loop repeatedly executes a block of code as long as a specified condition remains `True`. | <pre>Example: count = 0 while count < 5: print(count) count += 1</pre> | |
